Fig. 18.1 The boom-and-bust cycle. (A) The fluctuation in frequencies of three resistance genes in variety X (green), Y (blue) and Z (red). (B) The fluctuation in the corresponding virulence genes in the pathogen population. (L. Munk.)

Fig. 18.2 Disease development in plant varieties with different resistance genes. (A) A variety without resistance genes. (B) A variety with an effective race-specific resistance gene. (C) A variety with race-non-specific resistance or a variety mixture composed of several varieties each possessing a resistance gene. (© J. Yuen.)

Fig. 18.3 A potato mixture exposed to natural inoculum and composed of four varieties with different levels of resistance. (© L. Munk.)

Fig. 18.4 A schematic illustration of a three-way cereal mixture, where the 'red', 'black' and 'blue' plants carry three different resistance genes to an airborne pathogen. The airborne population consists of spores possessing virulence genes corresponding to the resistance gene, i.e. 'red' spores are able to infect 'red' plants, etc. (© L. Munk.)
